Lecture: **Dr. WONG, Helena**

- Office: YEUNG-Y7712
- Lecturer: CA1/CF1
- Lab tutor: LA\*
- Email: [cshwong@cityu.edu.hk](mailto:cshwong@cityu.edu.hk)

### Agenda:

\* **Warm-up exercises (see below)**

\* Lecture 2 - Values and Variables.ipynb

\* Lecture 2 - Expressions and Arithmetic.ipynb

### Students may try these Warm-up / Break-time exercises:

#### Q1:

Please create a new notebook for Python, e.g. Untitled.ipynb

Try: type and run **10+6\*4**

Try: type and run **2\*\*3\*\*2**

**Notes/Tips:** You may either

- you may type `print(10+6*4)` in a cell and run it
- or simply type `10+6*4` in a cell and run it

- But typing two lines like `10+6*4`  
`2**3**2` in the cell, only the result for `2**3**2` will be shown.

#### Q2 (a): Try:

```
print('-----')
print('Hello, World!')
print('-----')
```

#### Q2 (b): Single quotes, Double-quotes, Triple-quotes

```
print('-----')
print("Hello, World!")
print("-----") # triple quotes
print("-----") # triple quotes
```

#### Q2 (c): The below uses only one print statement. It doesn't work

```
print('-----
Hello, World!
-----')
```

#### Q2 (d): Redo (c) using triple quotes

Q3: Given that `**` means "to the power of"

a): **10 + 6 \* 4** means?

10+(6\*4)? (10+6)\*4?

b): **2\*\*3\*\*2** means?

2\*\*(3\*\*2)? (2\*\*3)\*\*2?

c): **10 - 6 - 4** means?

10-(6-4)? (10-6)-4?

**Notes/Learning:**

- a) Precedence: \* is higher than +
  - b) \*\* has Right-associativity or we say "right-to-left-associativity"
  - c) - has Left-associativity or we say "left-to-right-associativity"
- also for +, etc.

**d) Consider 5\*6 + 3 \*\* 7,**

Will python do 5\*6 or 3\*\*7 first?

**Answer: 5\*6 is done first (not 3\*\*7)**

**Student asks: "But \*\* has higher priority (precedence)!!"**

Explanation:

The evaluate of an expression is based on its structure (a binary tree)

precedence (priority) **doesn't mean run FIRST or run NEXT**  
precedence (priority) **is for grouping** (how the expression structure is parsed)

In 5\*6 + 3 \*\* 7,

\*\* has higher precedence than +.

Therefore the result of 3\*\*7 becomes an operand of +.

That is:

- i) \*\* has highest priority. So, \*\* first takes 3 and 7 as its operands.
- ii) \* and + are left. Because \* has higher priority, \* can then take 5 and 6.
- iii) Finally + takes its operands: (5\*6) and (3\*\*7)

Well, for (5\*6) + (3 \*\* 7), you and me will do 5\*6 first, agree? Same concept for Python ^\_^

**Conclusion: There are actually 2 steps:**

Step 1: understand 5\*6 + 3\*\*7 as (5\*6) + (3 \*\* 7)

Step 2: based on (5\*6) + (3 \*\* 7), calculate the left side (5\*6) to get 30, then calculate the right side (3\*\*7) to get 2187, then add 30 and 2187 to get 2217.

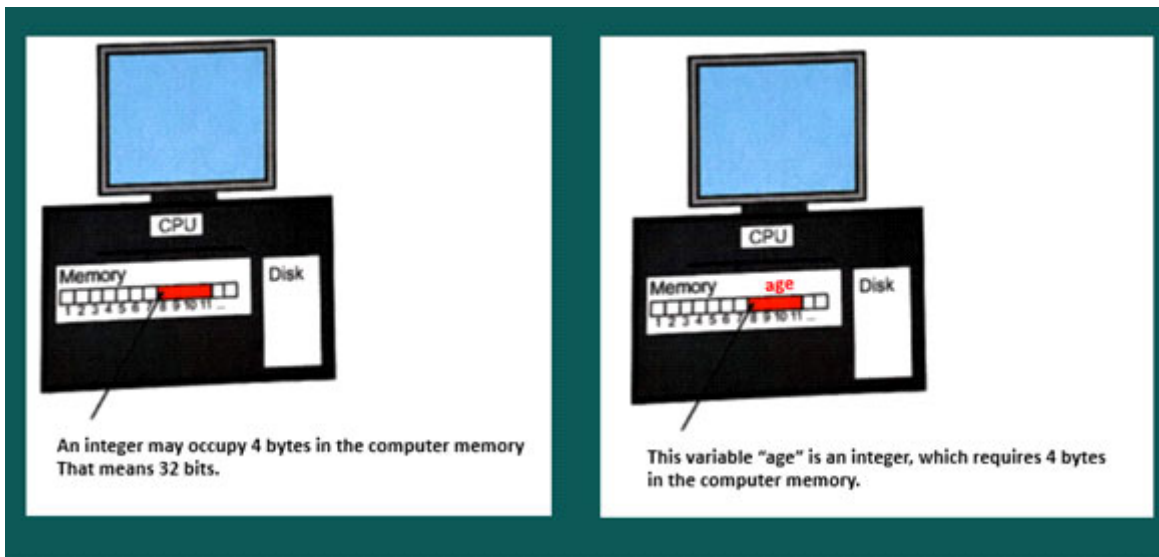

**Q4:** What are the following:

```
10**0.5, (10**0.5)**2
10==10, 10==10.0, 10==10+0.01, 10==(10**0.5)**2
import math
math.isclose(10, 10.0001), math.isclose(10, (10**0.5)**2)
```

**Think:**

When I borrow \$2 from you. Then I return \$1.1. The record says I still own you \$0.89999.  
When I return you \$0.9, the record is not made zero.  
What if similar is done in banking system?

3 kinds of program errors:

- (1) **Syntax error** (cannot convert to runnable code to even start running)
- (2) **Runtime error** (code stopped during running)
- (3) **Logical error** (can finish, but wrong output)

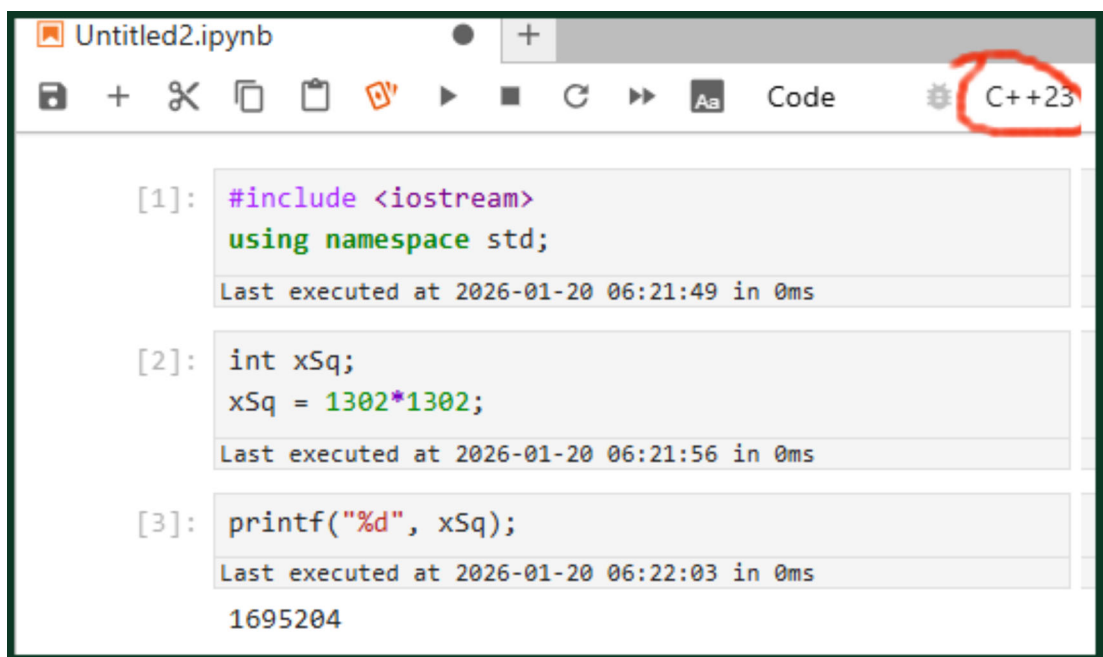

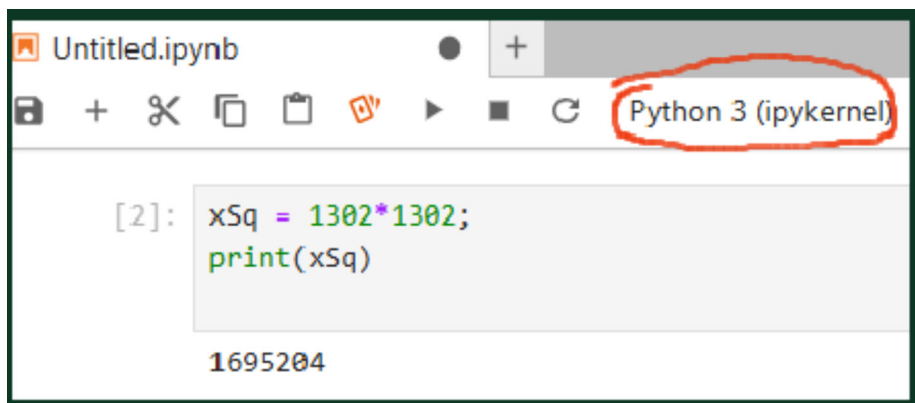

Python is a strongly-and-dynamically-typed language:  
(c++ strongly-and-statically-typed language)

==== Python =====

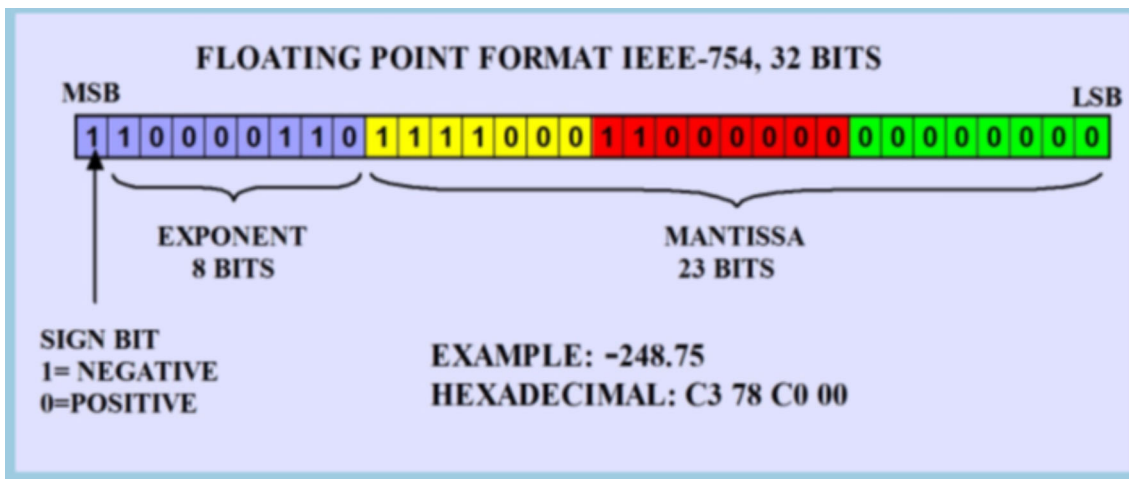

```
xSq = 1302*1302;
print(xSq)
===== C++ =====
#include <iostream>
using namespace std;

int xSq;
xSq = 1302*1302;

printf("%d", xSq);

**Expressions and Arithmetics**  
=====

<https://www.puntofotante.net/FLOATING-POINT-FORMAT-IEEE-754.htm>

**Internal representation of Floating point numbers (able to handle very small or very large):**

The number is translated to

one point something times two to the power of something (in binary)

e.g. -248.75 => -1.xxxx \* 2<sup>yyy</sup>

The exponent (8 bits) stores yyy+127 (so that yyy can be -127 to +127)

The mantissa (23 bits) stores xxxx

The sign bit is 1 or 0 for -ve or +ve

"I have \$1234891234.234189"

=> (If only the 5 most significant digits are stored):

\$1234800000.000000

What is 0.7<sub>10</sub> in binary?
